

Algebraic proof

A formula for prime numbers

What is a prime number?

Write down the first 12 prime numbers.

Here is a formula for the prime numbers, where n is a whole number (1,2,3) and P is a prime number

P = 6n - 1 and P = 6n + 1

So, when n = 1 P = 5 and 7 **5 and 7 are both prime numbers**

Check if the formula works when

n = 2 n = 3 n = 4

n = 5

Did you get a prime number every time?

If you found one value of n that doesn't give you a prime number, then the formula doesn't work. Often, it is easier to prove a formula isn't true than to prove that it is true.

Here is another formula for prime numbers:

$P = n^2 + n + 41$

Choose some values for n. Does it always work? How do you know? (to help you, the first 75 prime numbers are written on the last page)

To prove a rule algebraically, you have to be able to prove it works every time, for every value of n. One example where it does not work is enough to say rule isn't true Lots of examples where the rule does work is not enough to prove the rule is true You need a way to show that the rule works for every possible value of n.

Lots of people have tried to find a formula for prime numbers. Some of these formulae look really complicated and seem to work for a lot of values of n, but so far no-one has found one that works for every value of n. So, if you have nothing to do next weekend.... (but don't waste too much time on it!)

In GCSE maths you may be asked to prove something a bit simpler, like this:

Prove that the difference between the squares of two consecutive odd numbers is always a multiple of 8

Once you understand it, follow the rule using algebra.

Your solution should look something like this:

Let n be an integer (a whole number)

Then 2n would be an even number and (2n+1) would be an odd number

Consecutive odd numbers increase by 2 so (2n+3) would be the next odd number after (2n+1)

$$(2n+3)^{2} - (2n+1)^{2} = (2n+3)(2n+3) - (2n+1)(2n+1)$$

= 4n² + 12n + 9 - (4n² + 4n + 1)
= 4n² + 12n + 9 - 4n² - 4n - 1
= 8n + 8
= 8(n+1) which is a multiple of 8 as required

Λ

Try this one:

Prove that the sum of the squares of two consecutive even numbers is always a multiple of 4

Let n be a whole number

How would you write an even number?

How would you write the next even number?

Now square the two even numbers and add them together (be careful with brackets)

Simplify your expression

Now write your expression as two factors (one of the factors must be 4)

Try this one by yourself:

The mean of three consecutive numbers is always the middle number

Now try this one:

The product of two consecutive odd numbers is always an odd number

Here is a nice little number trick (It may be helpful on your non-calculator paper)

To square a number that ends .5 follow these steps:

- 1. Multiply the whole number part by the next whole number
- 2. Write this down
- 3. Now put .25 at the end of your number

Check these answers on a calculator

Were they all right?

Why does this work? We can answer this question with a proof:

Let n be a whole number

Then $n.5^2$ is correctly written as $(n + 0.5)^2$

 $(n + 0.5)^2 = (n + 0.5)(n + 0.5) = n^2 + n + 0.25 = n(n+1) + 0.25$ as required

2	3	5	7	11	13	17	19	23	29	31	37	41	43	47
53	59	61	67	71	73	79	83	89	97	101	103	107	109	113
127	131	137	139	149	151	157	163	167	173	179	181	191	193	197
199	211	223	227	229	233	239	241	251	257	263	268	271	277	281
283	293	307	311	313	317	331	337	347	349	353	359	367	373	379
